

The Kidney

Role(s) in
homeostasis

Brandon Roberts, Ph.D.

A microscopic image of kidney tissue, showing a dense network of red and blue structures, likely representing the renal cortex and medulla. The red structures are more prominent and form a complex, branching pattern, while the blue structures are more diffuse and granular.

Learning Objectives

1. Summarize the functions and basic structure of the kidney
2. Identify the three processes of urine formation
3. Explain how each structure of the nephron contributes to water-salt balance

A microscopic image of kidney tissue, showing a dense network of red and blue structures, likely representing the renal cortex and medulla. The red structures are more prominent and form a complex, branching pattern, while the blue structures are more diffuse and granular.

Learning Objectives

1. Summarize the functions and basic structure of the kidney
2. Identify the three processes of urine formation
3. Explain how each structure of the nephron contributes to water-salt balance

Functions of the Kidney

- **Remove waste** products from the body
- Maintain **acid-base** (pH) and **water-salt** balance
- Regulate **blood pressure**
- Promote production of **red blood cells**
- Activate **vitamin D**

Maintain **homeostasis** despite changes in endogenous production and dietary intake

Components of Homeostasis

Electrolytes - sodium, potassium, chloride

Minerals - calcium, phosphorus, magnesium

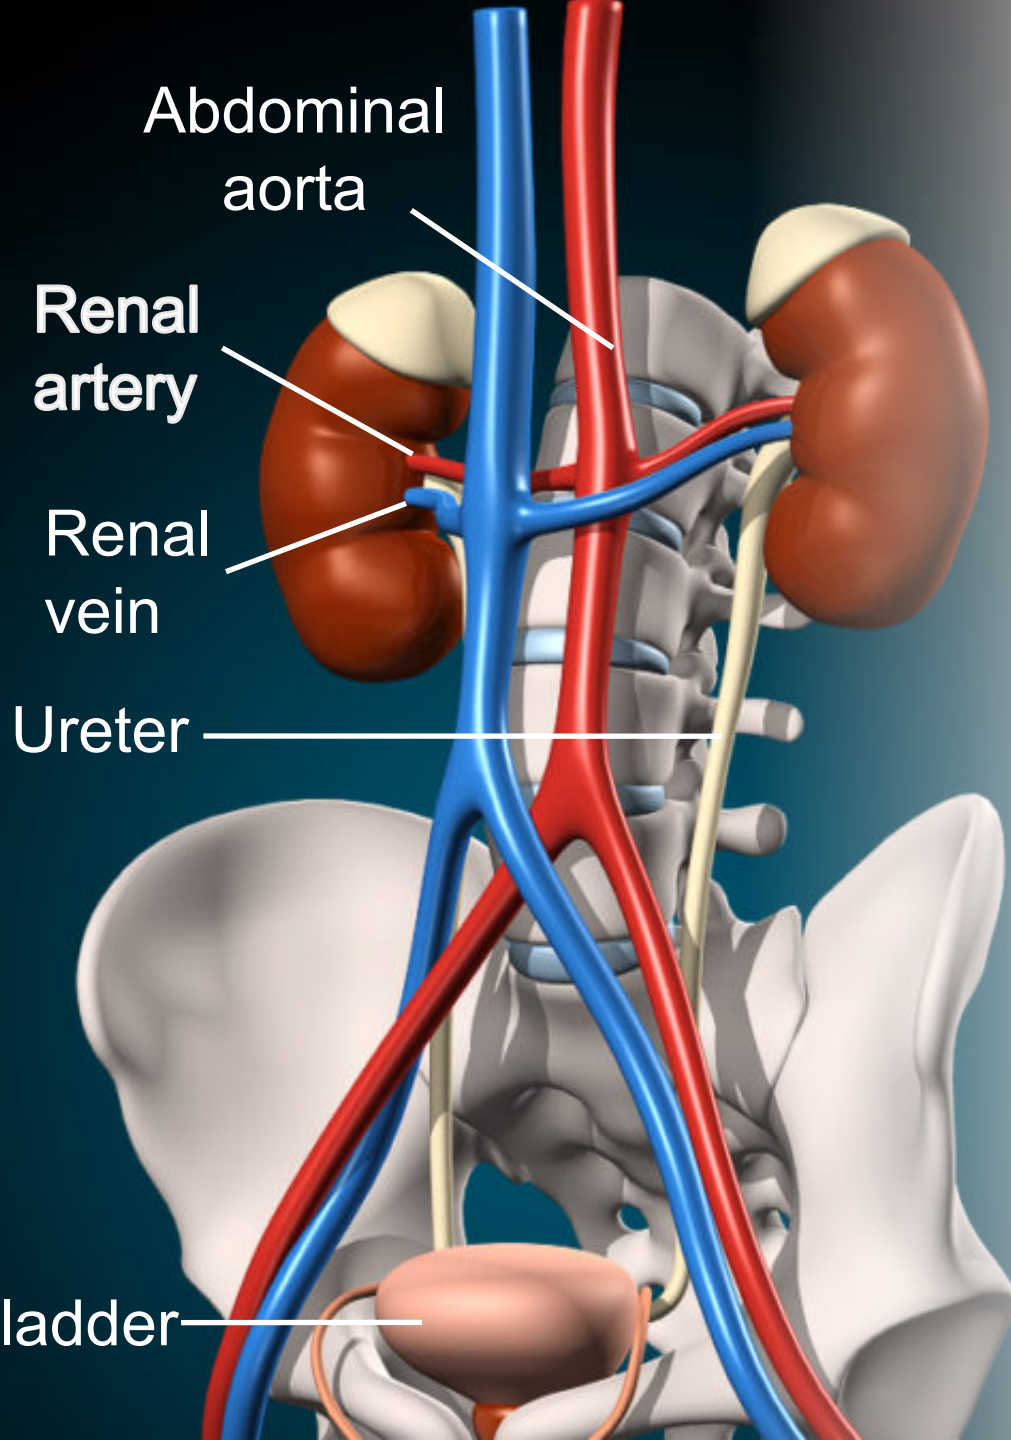

Water - (osmolality)

Acid-base – carbonic acid and bicarbonate

Waste material - urea (protein), creatinine (muscle), uric acid (nucleic acids)

Renal system

Input:

- Circulation

Output:

- Circulation
- Urinary tract

Renal Clearance

$$C_s = \frac{U_s \times V}{P_s}$$

Input:

- Circulation

Output:

- Circulation
- Urinary tract

C_s – Clearance of substance

U_s – Urine concentration of substance

P_s – Plasma concentration of substance

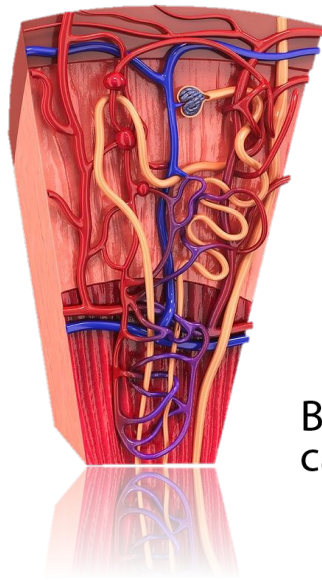

V – Urine flow rate

Kidney Structure

- **Renal cortex** - outer layer that receives blood from the **renal artery**
- **Renal medulla** – inner layer that consists of the **renal pyramids**
- **Renal pelvis** - a central waste collection space that is continuous with the **ureter**

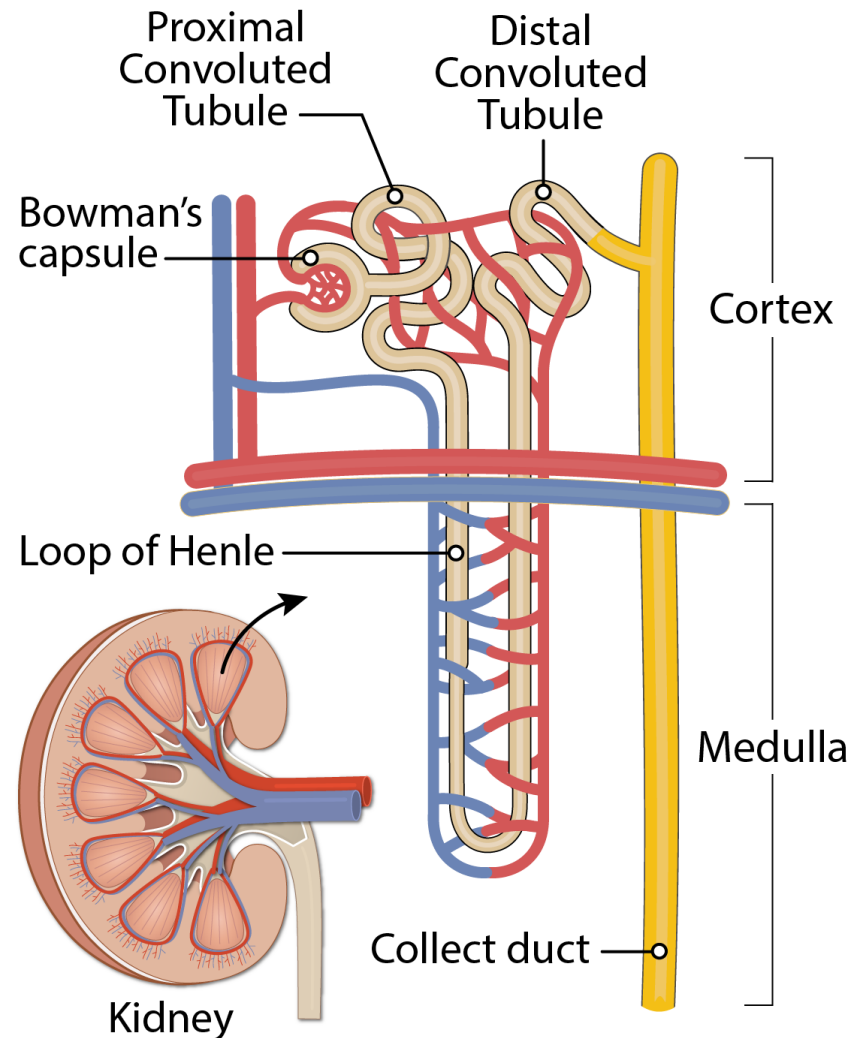

Nephron

Nephron - microscopic filtration unit of kidneys

- Filter blood and produce urine
- Several nephrons empty urine into one **collecting duct**
- The collecting ducts empty into the **renal pelvis**

A microscopic image of kidney tissue, showing a dense network of red and blue structures, likely representing the renal cortex and medulla. The red structures are more prominent and form a complex, branching pattern, while the blue structures are more diffuse and granular.

Learning Objectives

1. Summarize the functions and basic structure of the kidney
2. Identify the three processes of urine formation
3. Explain how each structure of the nephron contributes to water-salt balance

Three processes of urine formation

$$\text{Excretion} = \text{Filtration} - \text{Reabsorption} + \text{Secretion}$$

Three processes of urine formation

Glomerular Filtration:

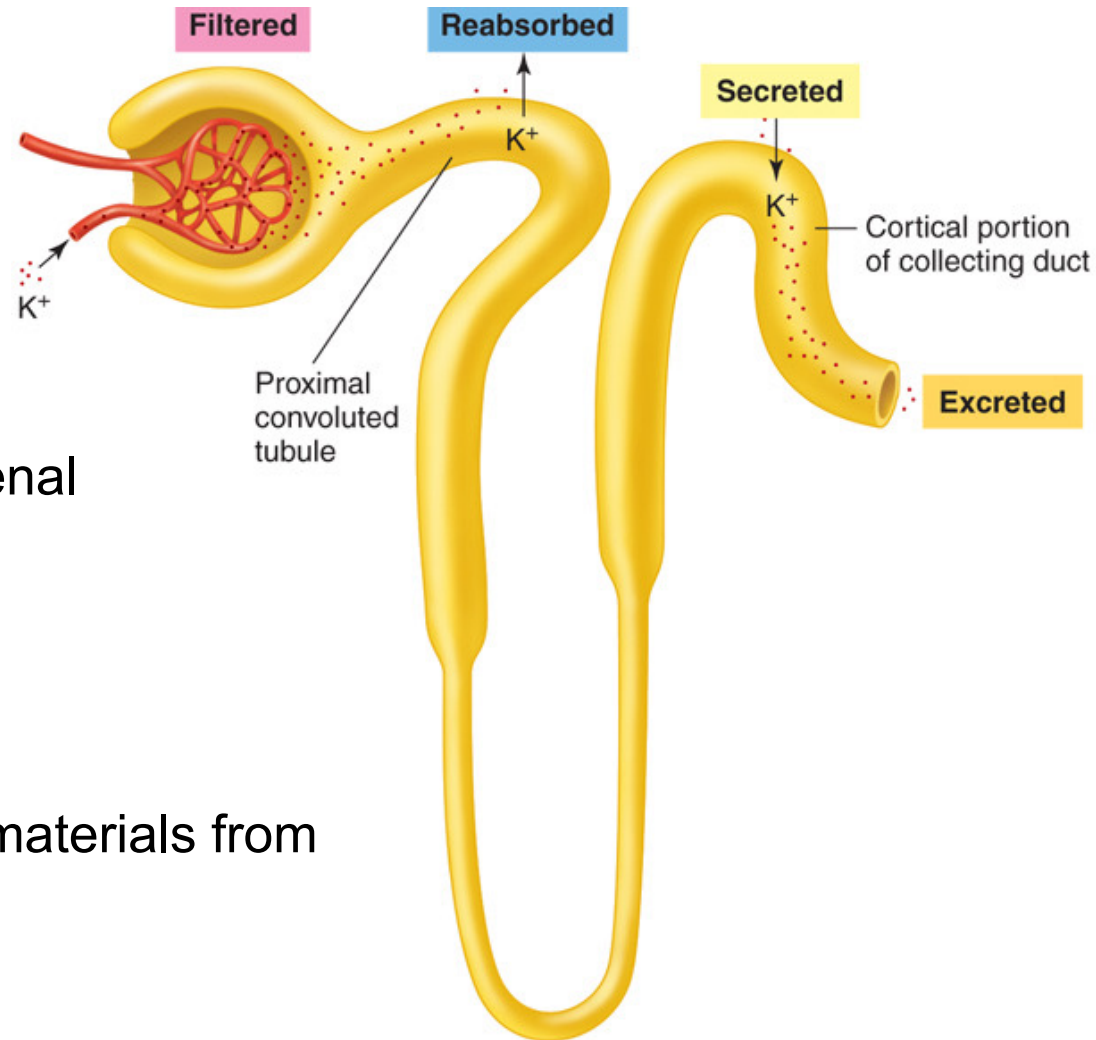

movement of materials from glomerulus into nephron

Tubular Reabsorption:

movement of nutrients from renal tubules back into blood

Tubular Secretion:

movement of wastes/excess materials from blood into renal tubules

Glomerular filtration

Glomerulus

fenestrated capillaries that pass:

- Electrolytes
- Glucose
- Amino acids
- Water

basement membrane that passes:

- (+) charged molecules
- Neutral charged molecules

Results in production of **ultrafiltrate**

Glomerular filtration

~ 180 L/day of **ultrafiltrate** produced; only 1–2 L of urine excreted/24 hours

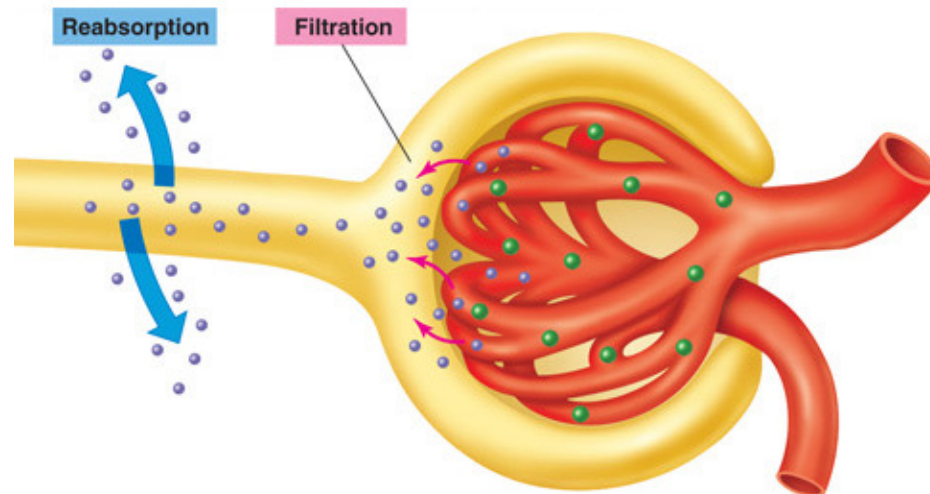

Urine volume varies according to needs of body

Majority of ultrafiltrate undergoes **tubular reabsorption**

Tubular reabsorption

- **Reabsorption** – process by which water and salts are move from the nephron back into the blood
- Reabsorption **decreases** renal clearance

Tubular secretion

- **Secretion** is opposite of reabsorption - substances are transported into tubule and **excreted**
- Reabsorption **decreases** renal clearance; secretion **increases** clearance

Three processes of urine formation

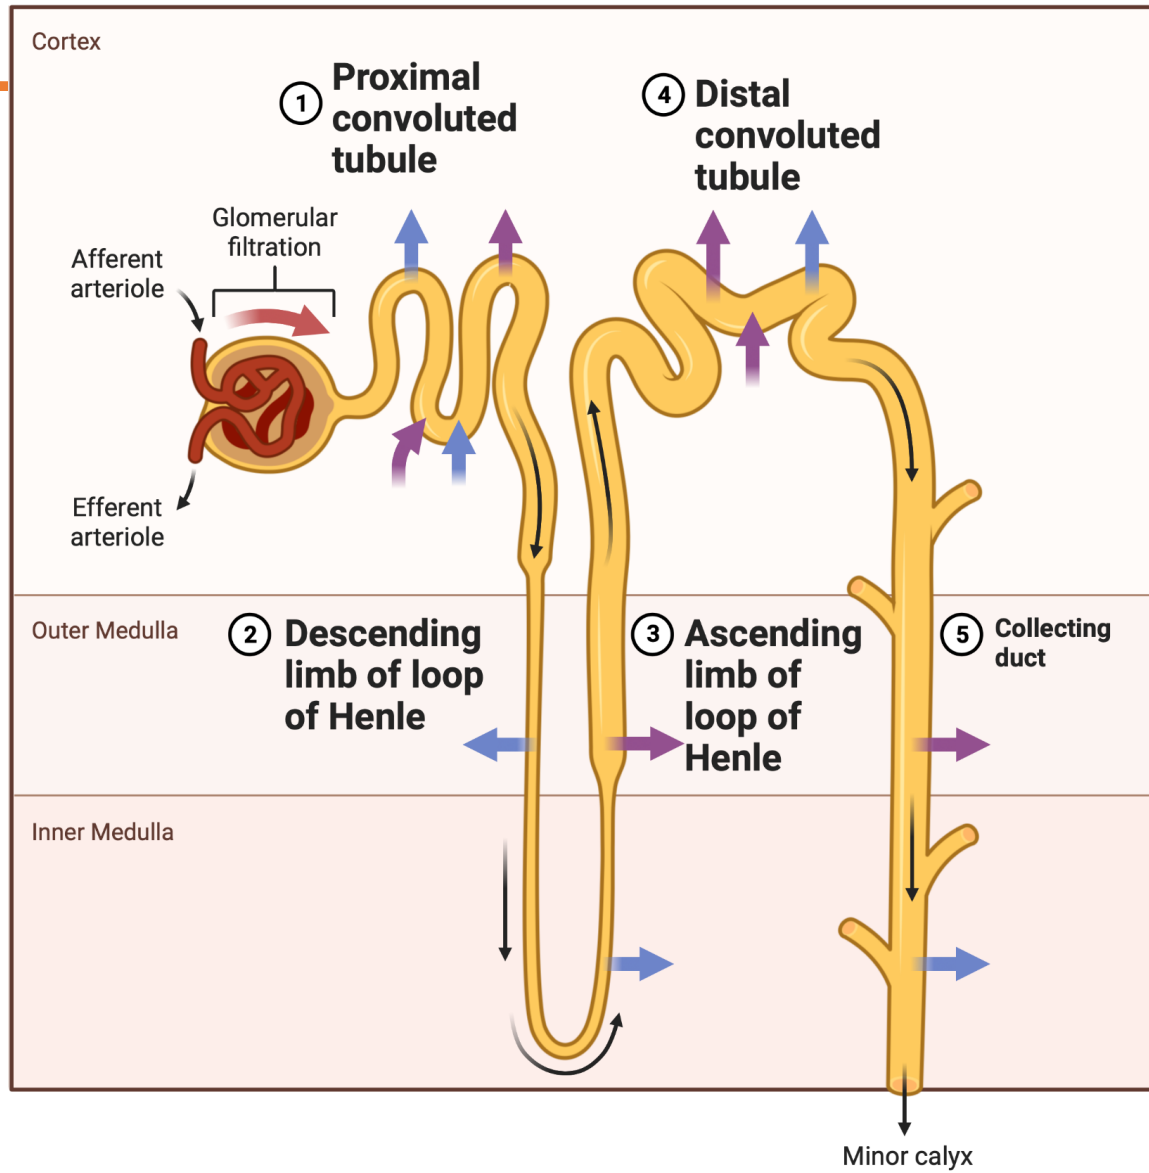

A microscopic image of kidney tissue, showing a dense network of red and blue structures, likely representing the renal cortex and medulla. The red structures are more prominent and form a complex, branching pattern, while the blue structures are more diffuse and granular.

Learning Objectives

1. Summarize the functions and basic structure of the kidney
2. Identify the three processes of urine formation
3. Explain how each structure of the nephron contributes to water-salt balance

Kidneys regulate water-salt balance

Proximal convoluted tubule

Ultrafiltrate is isosmotic to blood
(~300 mOsm/L)

Reabsorption of H₂O by osmosis
cannot occur without **active transport**
(AT) of Na⁺

- Loss of (+) charges causes Cl⁻ to passively follow
- Water then follows salt by osmosis

Proximal convoluted tubule

Ultrafiltrate is isosmotic to blood
(~300 mOsm/L)

Reabsorption of H₂O by osmosis
cannot occur without **active transport**
(AT) of Na⁺

- Loss of (+) charges causes Cl⁻ to passively follow
- Water then follows salt by osmosis

Loop of Henle

Descending Limb Loop of Henle

- Is permeable to H₂O
- Is impermeable to, and does not actively transport, salt
- Deep regions of medulla are **hypertonic**
- H₂O diffuses out of filtrate into interstitial fluid
- H₂O is then collected by capillaries

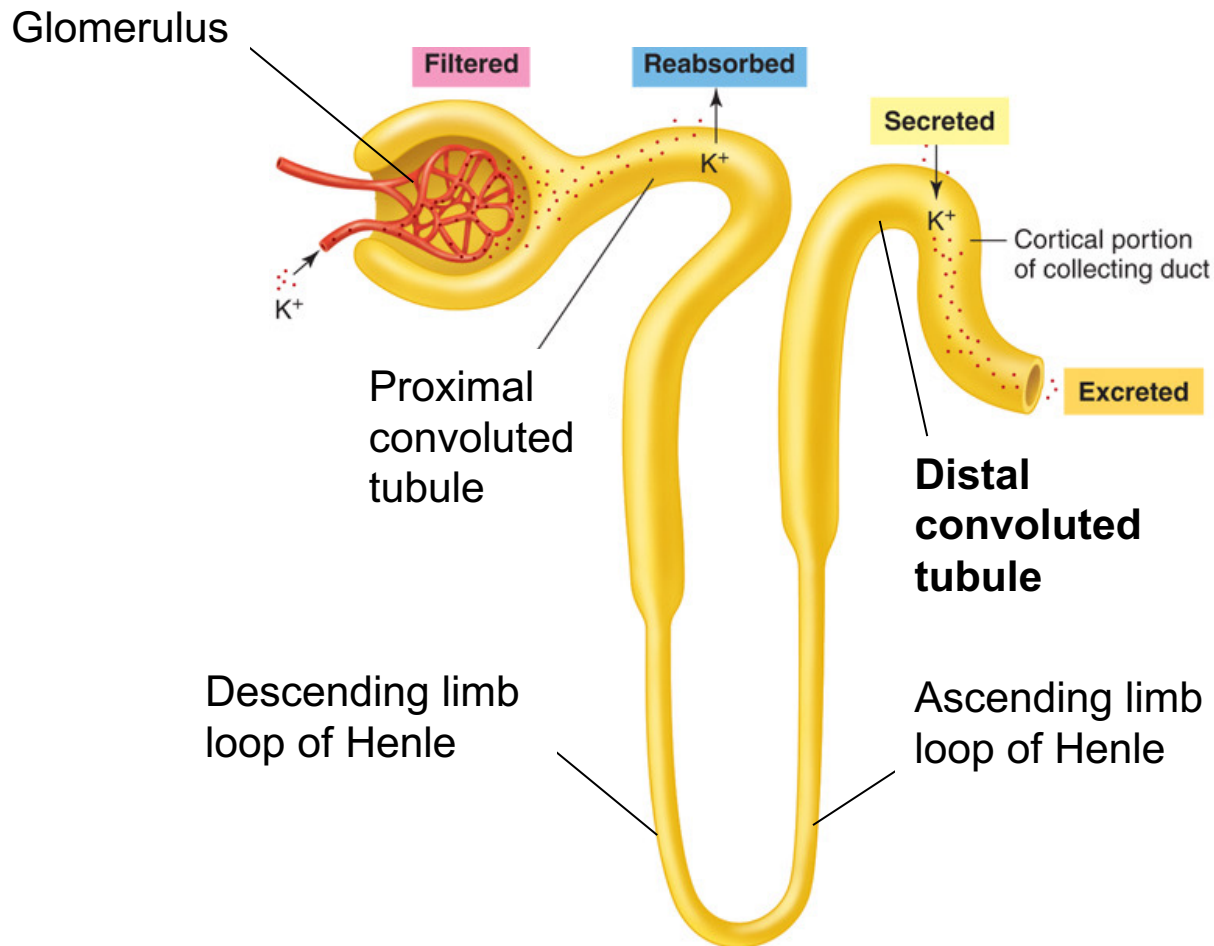

Ascending Limb Loop of Henle

- Impermeable to H_2O , but **permeable to salt**
- thick walls provide **active transport** of salt out of filtrate
- AT of salt causes interstitial fluid to become hypertonic to ultrafiltrate

Distal convoluted tubule

Distal convoluted tubule

Primary function:

- **Secretion** from blood plasma to filtrate
- Secreted ions:
 - Potassium (K^+)
 - Acid (H^+)
- Reabsorption of water influenced by hormones
- Empties into **collecting duct**

Filtration →

- H₂O
- Salts (NaCl, etc.)
- HCO₃⁻
- H⁺
- Urea
- Glucose
- Amino acids
- Some drugs

Reabsorption and secretion

Active transport →

Passive transport →

A microscopic image of kidney tissue, showing a dense network of red and blue structures, likely representing the renal cortex and medulla. The red structures are more prominent and form a complex, branching pattern, while the blue structures are more diffuse and granular.

Learning Objectives

1. Summarize the functions and basic structure of the kidney
2. Identify the three processes of urine formation
3. Explain how each structure of the nephron contributes to water-salt balance

Thank you!

Supplemental Material

A circular inset on the left side of the slide shows a microscopic view of several red blood cells. The cells are biconcave and appear as bright red, oval shapes against a dark background.

Kidneys and blood pressure

When blood volume (and, therefore, blood pressure) falls too low for filtration to occur, the juxtaglomerular apparatus can respond by secreting **renin**.

Renin

Renin - an enzyme that leads to the secretion of aldosterone by the adrenal glands.

Renin-angiotensin-aldosterone system (RAAS)
